ABSTRACT

Malignant melanoma is the most aggressive form of skin cancer. Metastatic dissemination in distant organs is one of the hallmarks of melanoma progression. Immunosuppression and tumour escape from immune surveillance are thought to be the major factors responsible for the establishment and progression of melanoma; however, the exact mechanisms leading to decreased anti-tumour immunity are not completely understood. We aimed to analyse the anti-tumour immune response during hematogenous metastasis using a B16-F1 metastatic melanoma model in C57BL/6 mice. At 21 days after tumour cell inoculation, rapid metastatic melanoma growth was observed, reflected through the increased incidence, number and size of metastatic colonies in the lungs (B16-F1). Phenotypic analyses of splenocytes revealed an increased percentage of CD3+T cells, a markedly reduced percentage of CD19+ B cells and an increased percentage and absolute number of CD4+Foxp3+ T regulatory cells. The cytotoxic activities of total splenocytes and isolated NK cells were significantly decreased in tumour-bearing mice. Thus, the metastatic progression of melanoma in this model is associated with diminished NK cytotoxicity, which may be due to an increased expansion of suppressive CD4+Foxp3+ T regulatory cells in the spleen.

Keywords: B16-F1, malignant melanoma, metastasis, NK cells, T regulatory cells

SAŽETAK

Maligni melanom je najagresivnija forma tumora kože. Diseminacija metastatskih celija u udaljene organe je glavna karakteristika progresije melanoma. Smatra se da su imunosupresija i izbegavanje imunskog nadzora glavni faktori odgovorni za uspostavljene metastaze, ali precizni mehanizmi odgovorni za oslabljen antitumorski imunski odgovor nisu u potpunosti razjašnjeni. U ovoj studiji, korišćenjem eksperimentalnog modela metastatskog melanoma (B16-F1) u C57BL/6 miševima analizirali smo antitumorski imunski odgovor u toku hematošenih metastatskih procesa. Dvadeset prvog dana nakon ubrizgavanja tumorskih ceлиja detektovan je ubrzan rast metastaza malignog melanoma što se ogleda u povećanoj incidenciji, broju i veličini metastatskih kolonija u plućima. Fenotipska analiza splenocita ukazuje na povećan procenat CD3+ T limfocita, značajno smanjen CD19+ B limfocita, značajno smanjen broj regulatornih CD4+Foxp3+ T limfocita. Citotoksička aktivnost ukupnih splenocita i NK ceлиja u slezini je statistički značajno smanjena u miševima kojima su ubrizgane ceлиje malignog melanoma. Dobijeni rezultati u ovom eksperimentalnom modelu ukazuju da metastatskoj progresiji melanoma značajno doprinosi smanjena ubilačka sposobnost NK ceлиja koja je najverovatnije posledica zabeležene ekspanzije imunosupresivnih regulatornih CD4+Foxp3+ T limfocita u slezini.

Ključne reči: B16-F1, maligni melanom, metastaze, NK ceлиje, regulatorni T limfociti
INTRODUCTION

Malignant melanoma is the most aggressive form of skin cancer. This disease arises from the malignant transformation of melanocytes, a complex process that involves the activation of multiple oncopogenes and the inactivation of tumour suppressor genes (1,2). Metastatic tumour cells are characterised by their motility, ability to invade the surrounding tissues and enter the bloodstream, ability to survive the transit through the body and their ability to colonise distant organs (3). The invasion of malignant melanocytes, with subsequent metastatic dissemination and tumour growth in distant organs or tissues, is the hallmark of melanoma progression (4).

The metastatic spread of tumour cells involves interactions between tumour and immune cells (5), during which immune cells could either eliminate tumour cells and attenuate the metastasis or facilitate the metastatic dissemination (6). The role of anti-tumour immunity in metastatic melanoma growth is not completely understood. CD8+ T cell–mediated immune cells could either eliminate tumour cells and attenuate interactions between tumour and immune cells (5), during which immune response in experimental melanoma models (7). However, in patients with melanoma, these melanoma-specific CD8+ T cells are not efficient in controlling tumour progression. Thus, it appears that the role of CD8+ cytotoxic T cells is variable and could be related to the immunosuppressed state associated with advanced tumours (8,9).

The immunosuppressive tumour microenvironment may be a major obstacle for the development of effective tumour-specific immune responses. Recent studies of malignant melanoma have demonstrated that the number of regulatory CD4+CD25+Foxp3+ T cells in the peripheral blood and within tumours is elevated, suggesting that these cells play a role in the induction of antigen-specific, local immune tolerance at tumour sites (10,11).

Natural killer (NK) cells, a key component of the innate immunity pathway, are cytolytic cells that recognise and kill malignant cells without prior sensitisation (12,13). NK cells are able to eliminate malignant cells from the circulation and thus serve as the earliest effectors against the dissemination of hematogenous metastasis [reviewed in (13)]. Natural Killer Group 2 Member D (NKG2D) is a powerful activating NK cell receptor that recognises various ligands on malignant transformed cells, such as MICA/B in humans and H60 and RAE-1 in mice (14). Natural regulatory T cells were shown to directly inhibit NKG2D-mediated NK cell cytotoxicity and suppress NK cell-mediated tumour rejection (15).

B cells are the effector cells of humoral immunity, and their role in antitumour immunity is not yet clear. Some studies suggest that these cells play a dual role in tumour-specific cellular immunity. For example, B cells can positively regulate cellular immune responses by serving as antigen-presenting cells and/or by providing costimulatory signals that can induce tumour-specific cytotoxic T cell activation (16-18). On the other hand, regulatory B cells (B10 cells) can negatively regulate inflammation and immune responses through the production of IL-10 (19-21). It has also been reported that B cells enhance premalignancy by potentiating chronic inflammation (22,23). The antibodies produced by activated B cells home to premalignant lesions and modulate chronic inflammation by cross-linking the FcR on resident leukocytes. This activity results in rapid degranulation and the release of proinflammatory mediators that further enhance the cascade of activation and recruitment of innate immune cells (23).

In the present study, we aimed to analyse anti-tumour innate and adaptive immune responses during hematogenous metastasis using the B16-F1 metastatic melanoma model in C57BL/6 mice.

MATERIALS AND METHODS

Mice

Eight to ten-week-old female and male C57BL/6 mice (purchased from the Military Medical Academy, Belgrade, Serbia) were used as model hosts for experimental metastatic melanoma. Mice were housed under standard laboratory conditions. The experiments were approved by the Ethics board of the University of Kragujevac Faculty of Medicine.

Murine melanoma cell line B16-F1

The murine skin melanoma cell line B16-F1, which is syngeneic to the C57BL/6 background, was purchased from the American Type Culture Collection (CRL-6323; ATCC, USA). The cells were routinely cultured as previously described (24,25).

Estimation of in vivo metastasis in B16-F1 mouse melanoma model

For inoculation, B16-F1 melanoma cells were harvested at ~90% confluency using 0.25% trypsin and 0.02% EDTA in phosphate buffered saline (PBS; PAA Laboratories GmbH). Cells were washed once in complete medium and twice in DMEM before inoculation. The viability of tumour cells was determined using the trypan blue assay, and only cell suspensions with ≥95% viable cells were used.

An experimental metastasis assay was performed by the intravenous injection of 5×10^4 B16-F1 cells, in a volume 0.2 ml, into the lateral tail vein of syngeneic C57BL/6 mice, as described previously (26). The mice were sacrificed on day 21 following melanoma cell injection, and lung, liver and brain tissues were removed for histological examination (24).

Splenic cell preparation

At 12 days after tumour cell injection, mice were sacrificed, and single-cell suspensions from spleens were obtained by mechanical dispersion through a cell strainer (BD Pharmingen, USA) in complete growth medium. Pellets were resuspended in red blood cell lysis solution, washed three times and resuspended in complete growth medium.

Phenotyping of splenocytes

The following anti-mouse mAbs were used: CD3, CD4, CD8, CD3e, CD19, F4/80 and NK1.1 (BD Pharmingen/
The percentage of cytotoxicity was calculated as: cytotoxicity (%) = \[1-(\text{experimental group (OD)}/\text{control group (OD)})\] × 100. The data were expressed as the mean±SD of triplicate wells. Cytotoxic capacity was also presented in lytic units, LU20/107 cells, which were calculated from the means of triplicates percentages of killing obtained at four different T:E ratios. The estimated numbers represent the mean values.

**Statistical analysis**

The data were analysed using SPSS version 13. Statistical significance was evaluated using the Student’s t-test. The normal data distribution was evaluated by the Kolmogorov–Smirnov test. The results were considered significantly different when p<0.05.

**RESULTS**

**The detection of metastatic melanoma growth in the lung**

Metastatic melanoma was established in syngeneic C57BL/6 mice by the intravenous injection of 5×10⁴ B16-F1 cells into the lateral tail vein. On day 21 following tumour cell injection, all mice were sacrificed, and the lungs, liver and brain were investigated for the presence of metastatic colonies. Metastatic colonies were evident in the lung tissue; eleven out of twelve mice (92%) developed numerous lung metastases, as shown in Figure 1A. Metastatic colonies were not observed in other parenchymal organs at this timepoint (data not shown).

**NK cell and CD8⁺ T cell separation**

NK cells were isolated from splenocyte suspensions by magnetic cell sorting. Single-cell suspensions of splenocytes were labelled using microbeads conjugated to monoclonal anti-mouse CD49b (DX5) antibodies (Miltenyi Biotec, USA) and positively selected as previously described (24). CD8⁺ T cells were negatively selected from single-cell suspensions of splenocytes using a Dynal mouse T cell negative isolation kit (Invitrogen) as previously described (27).

**Cytotoxicity assay**

The cytotoxic activities of splenocytes, adherent cells, CD8⁺ T cells and NK cells were measured using a 4-h MTT (3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide) assay. Isolated splenocytes, adherent cells, CD8⁺ T cells and NK cells were used as effector cells (E), and B16F1 melanoma cells were used as target cells (T). MTT cytotoxicity assays were performed as previously described (28).

Figure 1. Metastatic melanoma growth in the lungs of C57BL/6 mice, 21 days after inoculation with B16-F1 cells

Fresh frozen lung tissues were stained with hematoxylin and eosin (H&E) and examined by light microscope for the number and size of metastatic colonies. H&E-stained sections (4 mm) from at least three different levels were analysed. A. Histological section across the lung of a mouse bearing B16-F1 melanoma cells (original magnification 10×) showing metastatic colonies (arrows). B. Histology of a lung section from a mouse without lung metastasis.
We examined in vitro cytotoxic activity of splenocytes against tumour cells at the target–effector (T:E) ratios of 1:100, 1:50, 1:20 and 1:10. These cells were isolated before and on days 12 after i.v. injections of B16-F1 melanoma cells and were tested for cytotoxic activity against the melanoma cells using MTT assay. As shown in Figure 4A and 4B, cytotoxicity of total splenic cells was diminished after tumour cell injection.

To identify the type of effector cells that is responsible for the diminished cytotoxic capacity of splenocytes, we isolated adherent cells, CD8+ T cells and CD49b+ NK cells and tested their anti-tumour cytotoxicity. We did not find any differences in the cytotoxicity of adherent cells between naive and melanoma-bearing mice (Figure 4C and 4F). We next tested the cytotoxic activity of CD8+ T cells against tumour cells. As shown in Figure 4D and 4F, significant tumour-specific CD8+ T cell-mediated cytotoxicity was observed in control mice (p<0.05). Remarkably, we found that the cytotoxic activity of NK cells in the spleen was diminished after tumour cell inoculation (Figure 4E and 4F). The obtained results indicate that impaired NK cell cytotoxicity may be associated with diminished anti-melanoma immune response during hematogenous metastasis.

The total number of mononuclear cells in the spleen was not significantly affected after the injection of B16-F1 malignant melanocytes (data not shown). As shown in the left panel of Figure 2A, there was a statistically significant increase in the percentage of CD3+ T cells (p <0.05) due to the increase in the percentage of CD8+ cells (p<0.05; Figure 2B, left panel). Furthermore, the percentage of CD19+B cells was drastically reduced (p<0.05; Figure 2A, left panel). The absolute number of subsets (Figure 2, right panels) correlates with these findings, while the absolute number of CD19+B cells was again significantly reduced (p<0.05; Figure 2A, right panel). There were no significant changes in the percentages or absolute number of CD4+ cells, NK (CD3ε-NK1.1+) cells, or macrophages (F4/80+) in the spleen on day 12 after tumour inoculation (Figure 2B and 2C, left panel).

The number of CD4+Foxp3+ T regulatory cells in the spleen is elevated after melanoma cell inoculation

We next investigated whether the number of regulatory CD4+Foxp3+ T cells in the spleen is altered after melanoma cell inoculation. Flow cytometric analysis showed that the injection of melanoma cells resulted in a significant increase in the percentage and absolute number of CD4+Foxp3+ T cells (p<0.05; Figure 3). It appears that regulatory T cells may facilitate tumour metastasis by promoting an immunosuppressive environment.

A diminished NK cell-mediated anti-melanoma response in the spleen

We examined in vitro cytotoxic activity of splenocytes from naive and melanoma-injected C57BL/6 mice with a target–effector (TE) ratio of 1:100, 1:50, 1:20 and 1:10. These cells were isolated before and on days 12 after i.v. injections of B16-F1 melanoma cells and were tested for cytotoxic activity against the melanoma cells using MTT assay. As shown in Figure 4A and 4B, cytotoxicity of total splenic cells was diminished after tumour cell injection.

To identify the type of effector cells that is responsible for the diminished cytotoxic capacity of splenocytes, we isolated adherent cells, CD8+ T cells and CD49b+ NK cells and tested their anti-tumour cytotoxicity. We did not find any differences in the cytotoxicity of adherent cells between naive and melanoma-bearing mice (Figure 4C and 4F). We next tested the cytotoxic activity of CD8+ T cells against tumour cells. As shown in Figure 4D and 4F, significant tumour-specific CD8+ T cell-mediated cytotoxicity was observed in control mice (p<0.05). Remarkably, we found that the cytotoxic activity of NK cells in the spleen was diminished after tumour cell injection (Figure 4E and 4F). The obtained results indicate that impaired NK cell cytotoxicity may be associated with diminished anti-melanoma immune response during hematogenous metastasis.
DISCUSSION

In the present study, we observed rapid metastatic melanoma dissemination in the lung tissue (B16-F1), reflected through the increased incidence, number and size of metastatic colonies. Our data show that hematogenous metastasis is accompanied by an increase in the percentage of CD3+ T cells, which is most likely due to an increased percentage of CD8+ cells and a drastically reduced percentage of CD19+ B cells in the spleen. In our tumour model, diminished cytotoxicity of total splenic cells and NK cells is associated with an increase in the percentage and absolute number of CD4+Foxp3+ T regulatory cells. These results suggest that the spread of metastatic melanoma was mainly associated with decreased NK cell cytotoxicity, with a possible role for the suppressive activity of an increased proportion of Treg cells.

The B16 cell line is derived from a spontaneous tumour isolated from a C57BL/6 mouse. It is a highly aggressive tumour, and more importantly, it is similar to human melanoma in its propensity for metastasis and low MHC expression (30). In the current study, on day 21 following i.v. injection of B16-F1 (murine melanoma variant cell line), we demonstrated rapid metastatic melanoma growth in the lung tissue, reflected through an increased incidence, number and size of metastatic colonies. Eleven out of twelve C57BL/6 mice (92%) developed numerous lung metastases (Figure 1A).

The spleen, a secondary lymphoid organ, may be involved in the anti-tumour immune response, and a relationship between splenectomy and lung metastasis has been reported (31,32). We noticed that at 12 days after inoculation, the percentage and absolute number of CD3+ T cells were significantly increased in the spleen. This change is most likely due to the increased frequency of CD8+ cells, as the frequency and number of CD4+ cells was not altered. Interestingly, we noticed a marked reduction in the percentage and number of CD19+ B cells in the spleens of tumour-injected mice (Figure 1A), which could be required for optimal cellular immune responses against B16 tumours in vivo (33). DiLillo et al (33) reported that B cell depletion reduces the generation of effector/memory and cytokine-secreting CD4+ and CD8+ T cells as well as the activation and proliferation of tumour-specific CD8+ T cells. These data suggest that impaired T cell activation and effector-memory cell generation in the absence of B cells is likely to promote tumour growth and metastasis. It has also been reported that the number of NK cells and B cells in the bone marrow and spleen of tumour-bearing mice are reduced. This correlates with a decrease in the number of common lymphoid progenitors, suggesting that the tumour growth can lead to reduced lymphopoiesis (29). However, in our tumour model, we found a reduced number of B cells and an increased number of T cells, and we did not find any differences in the number NK cells or macrophages before and after injection of melanoma cells (Figure 2C).

The spleen, a secondary lymphoid organ, may be involved in the anti-tumour immune response, and a relationship between splenectomy and lung metastasis has been reported (31,32). We noticed that at 12 days after inoculation, the percentage and absolute number of CD3+ T cells were significantly increased in the spleen. This change is most likely due to the increased frequency of CD8+ cells, as the frequency and number of CD4+ cells was not altered. Interestingly, we noticed a marked reduction in the percentage and number of CD19+ B cells in the spleens of tumour-injected mice (Figure 2A), which could be required for optimal cellular immune responses against B16 tumours in vivo (33). DiLillo et al (33) reported that B cell depletion reduces the generation of effector/memory and cytokine-secreting CD4+ and CD8+ T cells as well as the activation and proliferation of tumour-specific CD8+ T cells. These data suggest that impaired T cell activation and effector-memory cell generation in the absence of B cells is likely to promote tumour growth and metastasis. It has also been reported that the number of NK cells and B cells in the bone marrow and spleen of tumour-bearing mice are reduced. This correlates with a decrease in the number of common lymphoid progenitors, suggesting that the tumour growth can lead to reduced lymphopoiesis (29). However, in our tumour model, we found a reduced number of B cells and an increased number of T cells, and we did not find any differences in the number NK cells or macrophages before and after injection of melanoma cells (Figure 2C).

![Figure 3. The injection of B16-F1 malignant melanocytes causes an increase in the percentage and number of CD4+ Foxp3+ T cells in the spleen of C57BL/6 mice](image)

A. Melanoma cell-inoculated mice have a higher percentage (p<0.05; 1.75±0.4 vs. 2.77±0.54, left panel) and absolute number of CD4+Foxp3+ T regulatory cells than do naive mice (p<0.05; 1.9±0.36 vs. 3.06±0.5, right panel). B. A diagram illustrating the percentage of regulatory CD4+Foxp3+ T cells on the 0th (light blue) and 12th day after i.v. injection of B16-F1 cells (dark blue). The data are presented as the mean±SD of at least four mice per group. Statistical significance was tested by the Student’s t-test.
It has been suggested that the interactions between malignant cells and immune cells in the tumour microenvironment create an immunosuppressive network that protects the tumour from immune attack, permitting tumour progression (34-37). Recent studies suggest that T regulatory (Treg) cells are important cellular components of an immunosuppressive network that stimulates tumour growth and metastasis (38). We showed that the injection of melanoma cells resulted in a significant increase in the percentage and absolute number of CD4+Foxp3+ T regulatory cells (Figure 3). It appears that Tregs may facilitate tumour metastasis by promoting the formation of the immunosuppressive environment. The depletion of Treg cells was shown to facilitate tumour rejection in animal studies, implying that these cells suppress immune response against tumour cells (39,40).

Next, we also noticed that the cytotoxic activity of total splenic cells was diminished by day 12 after melanoma cell injection (Figure 4A and 4B). To define the effector cells responsible for the diminished cytotoxic capacity of splenocytes, we isolated adherent cells, CD8+T cells and NK cells and tested their cytotoxicity against tumour cells. We did not find any difference in the cytotoxicity of adherent cells of naive and melanoma cell-inoculated mice (Figure 4C and 4F), but CD8+T cells from tumour-inoculated mice were more cytotoxic than those from naive mice (Figure 4D and 4F). Tumour immunity depends on factors other than T-cells, and numerous studies in hematopoietic and solid tumours have revealed that NK cell activation and cytotoxicity are related to patient outcome (41-43). Remarkably, we found that the cytotoxic activity of NK cells in the spleen was diminished in melanoma cell-inoculated mice. The data are presented as the mean percentages of specific cytotoxicity and LU20/107 cells, which was calculated from the mean percentages of killing in four different T:E ratios and the percentages of effector cells found in the spleen. The data are presented as the mean±SD from at least four mice per group. Statistical significance was tested by the Student’s t-test. N.S. (not statistically significant).
Taken together, our results suggest that melanoma suppress innate anti-tumour immunity and facilitate metastasis, in part due to the increased expansion of CD4+ Foxp3+ T regulatory cells in the spleen.
