ABSTRACT

The aim of this study was to determine the effect of lead, nickel and cadmium on the germination of barley seeds (*Hordeum vulgare* L.) of Jadran variety. Based on the percentage of germination, germination energy, and root and hypocotyl length, authors done an analysis of the effects of PbCl₂, NiCl₂, CdCl₂ solutions, in concentrations of 10³ mol/m³, 10² mol/m³, 10 mol/m³, 1 mol/m³, 10⁻¹ mol/m³, 10⁻² mol/m³. The results showed that germination and germgrowthin stress conditions which are caused by heavy metals depend on the type of metal and its concentrations. The most toxic effect of alltested solutions had CdCl₂, and the weakest toxic effect had PbCl₂.

Keywords: *Hordeum vulgare* L., Lead, Nickel, Cadmium, Germination.

INTRODUCTION

The harmful effects of heavy metals in soil are reflected in the entire ecosystem (Kabata-Pendias, 2011). By accumulation in soil, heavy metals are involved in biochemical processes of element circulation, and in food chains. As a consequence of an inadequate application of chemicals, artificial fertilizers, etc. in agriculture, an increased amount of heavy metals occurs in agricultural land, which leads to the manifestation of their phytotoxic and negative impact on the quality of plant products (Rajkovic et al., 2012., Djelic et al., 2012., Pesko et al., 2011). Plants that grow or which are cultivated on contaminated land present health hazard for animals and human population.

Maximum permitted levels (MPL) of hazardous and noxious substances in soil and irrigation water, which can damage or alter the agricultural production capacity and the quality of irrigation water, coming from discharges from factories, dumping, improper use of mineral fertilizers and preservatives plants, are regulated in the Republic of Serbia by the Rulebook on the allowed quantities of dangerous and harmful substances in soil and water for irrigation and methods of their testing. If land contains more than the maximum allowed levels (Tab.1), than it is not recommended for agricultural production. Barley is considered to be one of the oldest, most widespread cereal in Europe. It has been cultivated for over 10,000 years (Salamini et al., 2002).

The species of the genus *Hordeum* have a basic number of chromosomes 7. Grown barley *Hordeum vulgare* L. ssp. *vulgare* and its wild ancestor *H. vulgare* L. ssp. *spontaneum* (C. Koch.) Thell. are diploid species with 2n = 14 chromosomes.

All cultivated forms of barley belong to species *Hordeum vulgare* L., which is divided into three subspecies based on the number of developed classics (Kricka et al., 2012): double row

barley (*H. vulgare* ssp. *distichum*), transitional barley (*H. vulgare* ssp. *intermedium*), row barley (*H. vulgare* ssp. *polystichum*).

It has short vegetation, and it istolerantto low temperatures, drought, salts, and basic soil reaction (Poehlman et al., 1985).

In order to obtain higher yields and better grain quality, numerous tests are being carried out to create new varieties resistant to biotic and abiotic stress (Zhang et al., 2001). So far, 124 varieties of barley have been created in the Republic of Serbia (Madic et al., 2011).

Barley (*H. vulgare*) is the most widespread of all cereal. It has a very rich nutritional value because it contains a large amount of vitamin B complex, and vitamins A, E, K, D. It is an excellent source of vegetable fibers, proteins, phosphorus, magnesium, zinc, iron, etc. Only 200g of barley contain 55 % of the recommended daily amount of vegetable fiber. It is gluten free and easy to digest, and due to its medicinal properties it is recommended that people consume this valuable food frequently (Tanner et al., 2016).

Table 1. Maximum permitted levels.

Chemical elements	Maximum permitted levels in soil mg/kg soil	Maximum permitted levels in water mg/lwater
Cadmium	to 3	to 0.01
Lead	to 100	to 0.1
Nickel	to 50	to 0.1

The Jadran variety is spring barley which is cultivated during summer time. It is characterized by a low stalk and good resistance to lodging. The quality of the grain and malt is excellent. The aim of this study was to determine the effect of different concentrations of heavy metals Pb, Ni, Cd on the germination, germination energy, root length and hypocotyl of barley (*H.vulgare*) seeds of the Jadran cultivar.

EXPERIMENTAL

Materials and methods

The toxic effect of heavy metals on barley seeds of Jadran cultivar was investigated using a solutions of PbCl₂, NiCl₂, CdCl₂, prepared in distilled water, in 7 different concentrations as follows: 10³ mol/m³, 10² mol/m³, 10 mol/m³, 1 mol/m³, 10⁻¹ mol/m³, 10⁻² mol/m³ and 0 mol/m³ (control)

100 seeds were planted for each concentration. 7 petri boxes were used on the bottom of which the filter paper was loaded with: 7 different concentrations of each heavy metal. Petri boxes with seeds were placed in a thermostat at a temperature of + 22° C. The experiment was done in three repetitions.

The length of the root, hypocotyl, was determined on the fifth day after placement of the experiment.

Germination energy was calculated by the form:

$$\frac{\sum (n \times p)}{\sum m} \quad (1)$$

where: n - germination time (first day, second day...); p - number of germinated seeds; m- total number of germinating seeds (Komljenović & Todorović, 1998).

The analyzed parameters are shown in the mean values and were statistically processed by the method of analysis of variance using two-factor trial, and the significance of differences was tested by LSD test for P 0.05 and 0.01. For statistically process the results it was used SPSS Statistics program (SPSS 16 for Windows).

RESULTS AND DISCUSSIONS

The percentage of germination of spring barley (*H. vulgare*) seeds of the Jadran variety in distilled water (control) is 85% (Fig. 1). Increase of heavy metal concentrations significantly decreased the germination percentage of barley.

Lead content in soil is very variable. This variability is mainly caused by the parent substrate on which the soil was

Table 2. The percentage of germination of barley seeds (*Hordeum vulgare* L. varieties Jadran) in solutions of different concentrations of PbCl₂, NiCl₂, CdCl₂.

	10 ³ mol/m ³	10 ² mol/m ³	10 mol/m ³	1 mol/m ³	10 ⁻¹ mol/m ³	10 ⁻² mol/m ³
PbCl ₂	27%	45.5%	61.5%	70.5%	81%	83%
NiCl ₂	0%	42.5%	50%	71.6%	80%	79%
CdCl ₂	0%	11.5%	31.5%	46.6%	58.3%	70%
H ₂ O	85%					

Nickel is an essential element required for plant growth and iron resorption (Chen et al., 2009). It is part of the urease enzyme that hydrolyzes urea in plant tissues (Polacco et al., 2013). The main mechanisms by which plants take up Ni are passive diffusion and active transport (Ahmad & Ashraf 2011). Excess Ni affects the absorption of nutrients at the root, decreases plant metabolism, inhibits photosynthesis and transpiration, causes ultrastructural

modifications and oxidative stress (Chen et al., 2009). Nickel disrupts the Krebs cycle and electron transport in the process of oxidative phosphorylation. Nickel, unlike lead, has good motility in both xylem and phloem and in large quantities is accumulated in fruits and seeds. Leaves usually have the highest nickel content, the younger parts have a higher content than the older ones, and the seeds have a

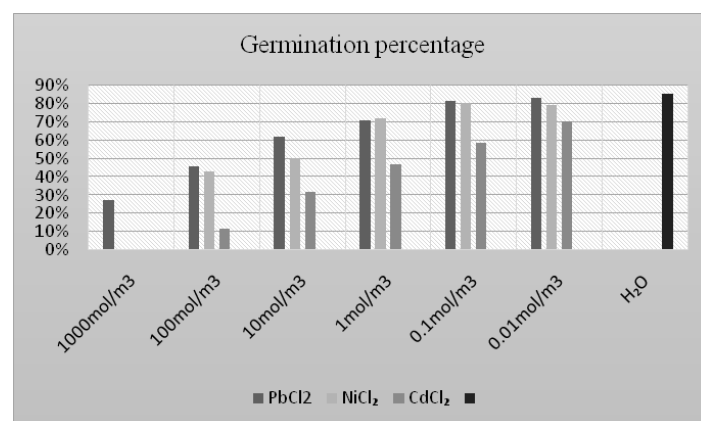

Figure 1. The germination percentage of barley seeds (*Hordeum vulgare* L. varieties Jadran) in solutions of different concentrations of PbCl₂, NiCl₂, CdCl₂

Research results from Azmat et al. (2006) show that lead inhibits germination of seeds, decreases germination percentage, germination index, and root/hypocotyl length in *Phaseolus mungo* and *Lens culinaris* species.

Our research (Tab. 2) shows that the PbCl₂ solution has the highest toxicity to germination of the seeds of spring barley (*H. vulgare*) of the Jadran variety at a concentration of 10³ mol/m³ where germination is reduced by 58% in relation to control. At the lowest concentration of 10⁻² mol/m³ seed germination was reduced by 2% compared to the control.

higher content than the straw..Nickel adversely affects not only the mobility or translocation of iron, but also its uptake.

Leone et al. (2005) indicate that the strongest toxic effect on seed germination has Ni in the form of NiCl₂, and weaker as Ni sulfate and Ni acetate.

The results of this study show that seeds of *H. vulgare*, Jadran varieties did not germinate in NiCl₂ solution, with concentrations of 10³ mol/m³ (Fig.1), so this concentration is lethal to seeds of this species. The sublethal concentration is 10² mol/m³ because it is the concentration in which 11.5% seeds germinate, which is 74% less than the control. NiCl₂ solution in concentrations from 10 mol/m³ to 10⁻² mol/m³ reduces the germination rate by up to 7% compared to the control (Tab. 1).

Cd is not an essential element for plants, but they adopt it (Porębska & Ostrowska, 1999). Cadmium absorbed from the nutrient medium is generally retained in the root. High concentrations of cadmium in plants inhibit respiration and electron transport in the process of oxidative phosphorylation, inhibit metabolism due to interactions with zinc, induce chlorosis and thus reduce the intensity of photosynthesis. The toxic effect of cadmium on plants has been the subject of numerous studies (Djelic et al., 2016, 2018; Ahmad et al., 2015; Shafi et al., 2010; Stankovic et al., 2010; Khan et al., 2006; Peralta-Videa et al., 2002; Jiang et al., 2001). The obtained results show that the germination of seeds of barley, Jadran variety, in the weakest Cd concentration is 15% less in comparison with the control, 13% less in comparison with the solution of the same Ni concentration and 9% less in comparison with the Pb solution. With increasing concentration of CdCl₂ solution, the germination percentage decreases drastically (Tab. 2). The lethal concentration is 10³ mol/m³.

Based on the toxic effect on the % germinated seeds of barley (*H. vulgare*), Jadran variety, we can compare the following: Cd > Ni > Pb.

The average root length on tested seeds of barley (*H. vulgare*) Jadran variety, in water (control) is 76.3 mm (Xmin - 18 mm, Xmax - 132 mm), and the mean hypocotyl length is 71.2 mm (Xmin - 19 mm, Xmax - 135 mm).

The lead solution exhibited the least toxic effect (Tab. 3) of all tested metals, on root and hypocotyl growth. The toxicity of PbCl₂ solution was more pronounced on root and hypocotyl length than of % germinated seeds. At a concentration of 10³ mol/m³, the root length is 3.1 mm, which is 73.2 mm, is 95.8% shorter than the control and the germination rate at this concentration is reduced by 58%. At a concentration of 10² mol/m³ the root length was 70.7 mm shorter than the control (Tab. 2), and the hypocotyl length 61 mm shorter than the control. Root length in solution of 10 mol/m³ is 33.1 mm (43.4%), concentration of 1 mol/m³ is 31 mm (40.6%), concentrations are 10⁻¹ mol/m³ by 23.1 mm (30.3%), concentrations are 10⁻² mol/m³ is 22.3 mm (29.26%) smaller than

in control. In all PbCl₂ tested solutions, there was a significant shortening of hypocotyl length (Tab. 4) relative to the control.

NiCl₂ has a stronger toxic effect on root growth and hypocotyl of barley germ than PbCl₂. A high level of toxicity can also be observed at a concentration of 10² mol/m³ since the measured root length at this concentration is only 2.3 mm, which is 74 mm (97%) less than the control. The length of the hypocotyl at this concentration is also small (1.6 mm). The solution in concentration of 10 mol/m³ has slightly weaker toxic effect where the root length is 7.9 mm which is 68.4 mm shorter than the control (Tab. 1) and the length of the hypocotyl is 38.6 mm which is 37.7 mm shorter than the control. If we compare with the values in the solution of PbCl₂ in concentration of 10 mol/m³, we will notice that the root length in the nickel solution is shorter by 35.3 mm and the hypocotyls by 33.2 mm shorter than the values measured in the lead solution.

This result indicates a stronger toxic effect of nickel than lead. The root and hypocotyl lengths at a concentration of 1 mol/m³ are 38.6 mm and 52.7 mm, which is 38 mm and 23.9 mm less than the control. and at this concentration NiCl₂ has a stronger toxic effect than PbCl₂. Concentrations of 10⁻¹ mol/m³ and 10⁻² mol/m³ have the least toxic effect, but they also significantly reduce root length and hypocotyl.

The root length of the germ of barley (*H. vulgare*), Jadran variety, at all concentrations of CdCl₂ solution is shorter than that in control. In the solution of concentration 10² mol/m³, the root was shorter by 98.8% compared to the control, compared to PbCl₂ by 4.6 mm and 82.1%, respectively, and by 1.3 mm and 56.2% shorter than NiCl₂. A significant decrease in root growth was also observed in the solution of concentration of 10 mol/m³, where the root length is 3.4 mm, which is 42.9 mm shorter than the control and 39.8 mm shorter than roots in PbCl₂ solution. A significant decrease in the root length of the germ of barley, Jadran variety, was also observed in solutions of 1 mol/m³, 10⁻¹ mol/m³, 10⁻² mol/m³ (Tab.3). The results shown in Tab.4. show that the development of hypocotyl at all tested CdCl₂ concentrations have a strong toxic effect.

Based on the toxic effect on the root length and hypocotyl of the germ of barley (*H. vulgare*), Jadran variety, all tested metals can be compared in the series: Cd > Ni > Pb.

Analyzing the variance of the two-factor trial and testing the significance of differences by LSD test for the P 0.05 and 0.01 risk level, we found that there were statistically significant to highly significant differences in root growth (Tab.3) and hypocotyl (Tab.4). The obtained results relate to all tested heavy metals and most of their concentrations compared with the control as well as for the interactions of heavy metals and concentrations.

Germination energy indicates seed quality. If the seeds germinate quickly and at a steady pace, better results are obtained in sowing, and the development of plant is more lush. It is actually a computerized method of utilizing data from the

germination log in which are entered the type and variety of seeds, the date of placement of the sample, the number of germinated seeds per day and the number of germinated seeds at the end of the test (Komljenović & Todorović, 1998). The smaller obtained number, the higher the seed germination energy, since more seeds germinated in shorter period of time.

Data on germination energy is important for practice because it indicates faster growth and independence of some cultivated plant species, which means that crops with higher germination energy will better resist the negative effects of initial growth.

Table 3. Root length (mm) of barley, Jadran variety, treated with heavy metal compounds $PbCl_2$, $NiCl_2$, $CdCl_2$.

<i>solution/ concentration</i>	<i>PbCl₂ (min.-max. mm)</i>	<i>NiCl₂ (min.-max. mm)</i>	<i>CdCl₂ (min.-max. mm)</i>

10^{-2} mol/m^3	54.2 (25-100)	66 (4-107)	47.9 (1-115)
Control	76.3 (19-135)	76.3 (19-135)	76.3 (19-135)
<i>LSD</i>	A-Concentratio of heavy metals	B- type of heavy Metal	AB
0,05	2.111	1.515	7.017
0,01	3.140	2.233	10.510

Table 4. Length of hypocotyl (mm) in barley of Jadran variety treated with heavy metal compounds $PbCl_2$, $NiCl_2$, $CdCl_2$

<i>solution/ concentration</i>	<i>PbCl₂ (min.-max. mm)</i>	<i>NiCl₂ (min.-max. mm)</i>	<i>CdCl₂ (min.-max. mm)</i>
10^3 mol/m^3	2,3 (1-15)	0 (0-0)	0 (0-0)
10^2 mol/m^3 ,	10.2 (1-28)	1.6 (1-5)	1 (0-1)
10 mol/m^3	41.8 (2-79)	8.6 (1-30)	31.6 (1-65)
1 mol/m^3	56.5 (1-105)	52.7 (3-110)	51.2 (2-105)
10^{-1} mol/m^3	57.2 (11-105)	62.1 (2-112)	52.8 (1-106)
10^{-2} mol/m^3	62 (25-100)	63.5 (4-107)	60.6 (1-110)
Control	71.2 (18-132)	71.2 (18-132)	71.2 (18-132)
<i>LSD</i>	A Concentration of heavy metals	B type of heavy metal	AB
0,05	1.277	1.459	4.812
0,01	2.462	2.690	5.440

The results obtained for the germination energies of barley seeds in solutions of different concentrations of PbCl₂, NiCl₂, CdCl₂ (Tab. 5) indicate that the tested solutions at all concentrations significantly reduce the energy of germination of

barley seeds (*H. vulgare*), Jadran variety. It is observed that germination energy decreases with increasing solution concentration.

Table 4. Comparative energy overview of the seed seeds in the solubility of various concentrations of PbCl₂, NiCl₂, CdCl₂.

	10 ³ mol/m ³	10 ² mol/m ³	10 mol/m ³	1 mol/m ³	10 ⁻¹ mol/m ³	10 ⁻² mol/m ³
PbCl₂	4.5	3.5	2.9	2.7	2.1	1.8
NiCl₂	0	3.9	3.1	3	2.3	1.9
CdCl₂	0	5	4.3	3.9	3	2
H₂O	1.5					

The germination energy in the control is 1.5. In a solution of NiCl₂, and CdCl₂ at a concentration of 10⁻² mol/m³ is the smallest decrease in germination energy. PbCl₂ solution has the weakest toxic effect compared to all tested metal. Seed germination occurred at all concentrations of this metal. However, the development of the germ shows that the lead has a toxic effect. A particularly good indicator of its toxicity is germination energy. In the solution of concentration 10⁻² mol/m³ germination energy is 1.8. and this indicates that it takes longer for seeds to germinate than in control. The tested heavy metals at all concentrations showed a stronger toxic effect on germination energy than on germination percentage.

Based on the toxic effect on the germination energy of barley seeds (*H. vulgare*), Jadran variety, the tested metals can be compared in the following order: Cd > Ni > Pb.

In plants, these metals directly or indirectly cause a wide range of physiological and biochemical dysfunctions that lead to reduced yield (Amari et al., 2017). Cd, Pb, and Ni show phytotoxic effects on germination and germ development in *Lactuca sativa*, *Brassica oleraceae*, *Lycopersicon esculentum*, *Raphanus sativus* (Johnson et al., 2011), *Helianthus annuus* (Jadia & Fulekar, 2008).

CONCLUSION

Based on the results obtained by testing different concentrations of PbCl₂, NiCl₂, CdCl₂ solutions, on the percentage of germination, germination energy, root length and hypocotyl of the species (*Hordeum vulgare* L.), Jadran variety, it can be concluded that: barley seeds have significantly reduced germination in the presence of all tested heavy metals and germination length, root length and hypocotyl, as well as germination energy depend on the type of heavy metal and solution concentrations. The most toxic effect has Cd and the weakest toxic effect has Pb.
