Summary

Background: Epilepsy (EP) is a common neurological disorder which is characterized by excessive abnormal synchronization of neuronal discharges in the brain due to chronic recurrent seizures of multiple etiologies. Variety of microRNAs have been associated with the occurrence and development of EP. This study aimed to determine the aberrant expression of miR-378 and miR-575 in EP patients to validate their potential to distinguish EP from healthy patients.

Methods: RT-qPCR was used to determine the expressions of miR-378 and miR-575 from serum specimens of 106 EP and 103 control individuals. Clinical indicators between EP patients and controls were assessed. Based on surgical outcome, EP patients were further divided into Engel I–IV EP. The potentials of miR-378 and miR-575 in discriminating EP from healthy participants and predicting surgical prognosis were calculated by receiver operating characteristic (ROC) analysis.

Results: We found the miR-378 and miR-575 were significantly declined (P<0.001) in Engel I–II and III–IV EP patients with no difference in clinical parameters compared. Moreover, miR-378 and miR-575 displayed high sensitivity, specificity, and accuracy in distinguishing EP patients and predicting surgical outcomes. Moreover, after surgical treatment, miR-378 and miR-575 levels were increased compared with those at admission, suggesting their potentials in treatment response.

Keywords: miR-378, miR-575, human epilepsy, serum biomarkers

Kratak sadržaj

Rezultati: Utvrdili smo da su miR-378 i miR-575 značajno smanjeni (P < 0,001) kod pacijenata sa Engel I–II i III–IV EP bez razlika u upoređenim kliničkim parametrima. Šta više, miR-378 i miR-575 su pokazali visoku osetljivost, specifičnost i tačnost u razlikovanju EP pacijenata i predviđanju ishoda. Dalje, nakon hirurškog lečenja, nivoi miR-378 i miR-575 su povećani u poređenju sa onima pri prijemu, što ukazuje na njihov potencial u reakciji na lečenje.

Zaključak: miR-378 i miR-575 se mogu koristiti kao novi i neinvazivni serumni biomarkeri u EP sa EP od zdravih kontrolnih ispitanika i predviđanje hirurškog ishoda, otkrivajući nove uvide u epileptogenese i lečenje EP.

Ključne reči: miR-378, miR-575, epilepsija kod ljudi, serumski biomarkeri
**Introduction**

Epilepsy (EP) is a chronic brain disease with a long course that poses a severe threat to patients’ physical and mental health (1). Seizures caused abnormal synchronous neuronal discharges (2), resulting in transient brain dysfunction and abnormalities in neuronal apoptosis, necrosis, and neurological deficits (3). In addition, EP was characterized by transient, unpredictability, and recurrence (4). About half of epilepsy patients had their onset in childhood and teenage years (5). So far, magnetic resonance imaging (MRI) and electroencephalography (EEG) have been able to help diagnose and differentiate epilepsy, whereas the assessment of anti-epileptic efficacy depended on EEG (6). However, EEG is expensive and time-consuming, which is not suitable for frequent and quick applications (7). Therefore, it is imperative to explore non-invasive and economic biomarkers to monitor EP development and evaluate the effectiveness of anti-epileptic treatment.

MicroRNAs (miRNAs) are endogenous single-stranded small RNA with approximately 22–24 nucleotides in length (8). These miRNAs are highly conserved and play a post-transcriptional role in regulating gene expressions (9). Several miRNAs are released from cells and circulate in the blood, show resistance to various RNA digesting enzymes, and are not affected by storage time, pH, temperature, repeat freezing, and thawing (10). Because these are less affected by changes in the peripheral environment, miRNAs are used as biomarkers for various diseases, including epilepsy (11, 12). In recent years, there has been increasing evidence indicating that multiple miRNAs regulate EP. For instance, the expression of miR-106b-5p, let-7d-5p, miR-130a-3p and miR-146a-5p are upregulated in the serum of EP patients, while miR-15a-5p and miR-194-5p levels are downregulated (13). Moreover, miR-134 and miR-21-5p are downregulated among epileptic rats (14, 15). Meanwhile, multiple miRNAs have been associated with epileptogenesis and the progression of EP (16, 17). In a previous study, miR-378 and miR-575 are dysregulated during the onset of EP and post-treatment (18). However, the potential of miR-378 and miR-575 concerning EP diagnosis and outcome prediction remained unknown.

In the present study, we aimed to determine the aberrant expression of miR-378 and miR-575 in EP patients to determine the potential in differentiating EP from healthy individuals. Moreover, the dynamic changes of miR-378 and miR-575 during seizure onset and after surgical treatment were evaluated to validate their application in predicting EP surgical outcome.

**Materials and Methods**

**Samples collection**

A total of 106 individuals diagnosed with EP but remained untreated in Linyi Central Hospital were enrolled as the EP group from November 2017 to April 2020. The control group consisted of 103 healthy individuals who underwent a physical examination at our hospital during the same period. The EP group and the healthy group were age and sex-matched. All enrolled participants signed informed consent, and the Ethics Committee of Linyi Central Hospital approved the current study protocol. Inclusion criteria for the EP: (1) those who were eligible for primary EP according to the diagnostic and classification criteria of the International League Against Epilepsy (ILAE); (2) the time since the last seizure was less than 1 week; (3) organic lesions such as traumatic brain injury, developmental malformation of the brain, intracranial occupancy, and cerebral infarction were excluded by imaging examinations such as computed tomography (CT), MRI and EEG. In addition, EP patients with neurological and other systemic disorders, traumatic brain injury, or receiving psychotropic medications in the last three months were excluded.

5 mL of blood sample was collected from EP patients and healthy controls after fasting and kept at room temperature for 3 hours. Then, the supernatant was aspirated into a sterilized EP tube. The sample was then centrifuged at 3000 r/min at room temperature for 10 min. After centrifugation, samples were stored at -80 °C until use.

**RT-qPCR analysis**

The frozen serum samples, stored at -80 °C, were thawed at 4 °C in a refrigerator. 1.5 mL of each sample was dispensed in a centrifuge tube. Next, 1 mL TRIzol was added to each sample at room temperature for 5 min. After lysis, 200 μL of chloroform was added for 10 min and then centrifuged at 12,000 g for 15 min at room temperature. Afterwards, 1 mL of 75% alcohol was used to precipitate RNA and then centrifuged at 4 °C for 5 min at 7,500 g. After washing, the RNA was placed for 15 min to dry RNA. Finally, 20 μL DNase/RNase-free deionized water was added to dissolve the RNA extract. The samples were analyzed for RNA purity using a NANODROP 2000 spectrophotometer. Then, the reverse transcription kit, SuperScript R Enzyme Mix, was used to prepare cDNA. The RT-qPCR was performed in AXYGEN 0.2 mL 96-well PCR system with U6 RNA as the internal reference. The CT values of miR-378 and miR-575 were derived at the end of the amplification reaction by fluorometric quantification and analyzed using the 2-△△CT method. All the experiments were performed in triplicate.
Statistical analysis

The experimental data, for normal distribution and variance homogeneity, were expressed in the form of mean ± standard deviation ($\bar{x} \pm s$). SPSS 22.0 software was used to statistically analyze the data obtained from each group, and an independent t-test and chi-square test were used for quantification. P<0.05 was deemed statistically significant.

Results

Clinicopathological information of all participants

As shown in Table I, there were no significant differences in age, gender distribution, BMI, and smoking history between EP patients and healthy controls.

Down-regulated miR-378 and miR-575 expressions in serum samples in EP patients

We used RT-qPCR to analyze and measure the expression levels of miR-378 and miR-575 in serum samples from EP patients and healthy volunteers. As highlighted in Figures 1A and 1B, the expression of miR-378 and miR-575 were prominently increased in the EP group as compared with the healthy control ($**P<0.001$).

Engel grades were applied to discriminate EP patients regarding seizure response to surgical treatment. According to the guidelines, Engel I was defined as free of disabling EP; Engel II was rare seizure after surgery; Engel III was deemed worthwhile improvement of EP reduction after surgery; Engel IV was characterized as no improvement in seizure conditions. As depicted in Figures 2A and 2B, Engel III–IV EP patients had significantly lower miR-378 and miR-575 expressions than Engel I–II ($***P<0.001$), suggesting the potentials of miR-378 and miR-575 in predicting surgical outcome.

(B) AUC of miR-378 in differentiating Engel I–II EP patients from healthy volunteers. (C) AUC of miR-378 in differentiating Engel III–IV EP patients from healthy volunteers. (D) AUC of miR-575 in differentiating EP patients from healthy volunteers. (E) AUC of miR-575 in differentiating Engel I–II EP patients from healthy volunteers. (F) AUC of miR-575 in differentiating Engel III–IV EP patients from healthy volunteers.
Diagnostic performances of miR-378 and miR-575 in distinguishing EP patients from healthy controls

ROC analysis was conducted to evaluate the capabilities of miR-378 and miR-575 abnormal expressions in discriminating EP from healthy controls. As demonstrated in Figure 3A and 3D, miR-378 and miR-575 presented high accuracy, sensitivity, and accuracy in differentiating EP from healthy participants with the area under the curves (AUCs) of 0.8066 and 0.8177, respectively (cut-off value = 1.4964 and 1.5298). Moreover, the AUCs of miR-378 and miR-575 in distinguishing Engel I–II EP from healthy controls were 0.7336 and 0.7949, respectively. Additionally, the AUCs of miR-378 and miR-575 in distinguishing Engel III–IV EP from healthy controls were 0.9345 and 0.8933, with the cut-off value of 1.9696 and 1.6184. Collectively, these results suggested that miR-378 and miR-575 were implicated in epileptogenesis and monitoring EP occurrence.

Dynamic levels of miR-378 and miR-575 before and after surgical treatment

After surgical treatment, the dynamic changes of miR-378 and miR-575 in EP samples were detected using qRT-PCR assay. As shown in Figures 4A and 4B, the expression of miR-378 and miR-575 was augmented after treatment compared to those at seizure onset, implying that miR-378 and miR-575 may function as feasible biomarkers for EP treatment response (**P<0.001).

Surgical outcomes regarding miR-378 and miR-575 in EP

Giving that Engel grade could indicate the surgical outcome in EP, we further examine the AUCs of miR-378 and miR-575 between Engel I–II and Engel III–IV EP patients. As illustrated in Figure 5A, miR-378 could serve as an accurate and high sensitive biomarker for predicting EP surgical prognosis, with an AUC of 0.8985 and a cut-off value of 1.7326. On the contrary, miR-575 had no value in predicting EP surgery outcome with the AUC value of less than 0.8 (Figure 5B).

Discussion

Statistical reports showed that about 70 million people worldwide were affected by EP (19). In China, there were more than 9 million EP patients (20). The number of patients with refractory EP who have been treated regularly for more than 2 years was greater than 2 million, and the prevalence rate accounted for 7% of the world’s population (21). The clinical manifestations of epilepsy were diverse, and the typology was complex with 4 common features, seizure, repetitive, transient, and stereotyped (22). Current treatments for EP included medication, surgery, dietary modifications, and gene therapy (23). Clinical studies have shown that 70%–80% of new EP patients can be controlled with anti-epileptic drugs (AEDs), and 60%–70% of these patients can be discontinued after 2 to 5 years of treatment with AEDs (24). Some postoperative patients with EP still needed AEDs to control their symptoms.

Epileptogenesis is a process in which the inflammatory response, the formation of new synaptic and abnormal conduction pathways, and neuronal apop-
tosis were jointly involved (25, 26). Current studies have shown that a variety of miRNAs are involved in the development of EP. MiR-132 was the first identified miRNA in EP, and its increase led to the development of EP (27). Furthermore, it was found that miR-34a, miR-132, miR-146a, and miR-184 miRNA expression were upregulated after the seizure, further promoting the recurrence of EP (28). Meanwhile, miR-124 is decreased in EP, inhibiting seizure activity through targeting CREB1 (29). Our study found that miR-378 and miR-575 were significantly reduced in serum samples from EP patients in relation to those in healthy controls, which was consistent with a previous study. Similar to our study, another study reported that miR-378 serves as a prognostic biomarker in cholangiocarcinoma (30).

Meanwhile, the clinical utility of microRNA-378 as an early diagnostic biomarker of human cancers has also been documented (31). Furthermore, miR-378 in serum are potential biomarkers for renal cell carcinoma (32). Additionally, it has been found that miR-378 play a role in metabolism, angiogenesis, and muscle biology (33). Similarly, miR-575 serve as a diagnostic marker for metastatic breast cancer and pancreatic cancer (34, 35).

Meanwhile, the ROC analysis validated that miR-378 and miR-575 may be highly sensitive and non-invasive candidates for EP diagnosis. More importantly, according to the Engel guidelines and dynamic changes in miR-378 and miR-575 before and after surgery treatment, we confirmed the potentials of miR-378 and miR-575 in predicting surgery outcome and treatment response in EP as well.

To sum up, miR-378 and miR-575 were decreased in EP serum samples, functioning as feasible biomarkers for EP monitoring and predicting surgical prognosis.
